The file protocol allows you to pass files from the file system to MPlayer. You use the file protocol for loading in a few different ways. You can load files into MPlayer using the file protocol with just the mplayer command. You can also load a file into MPlayer using the file protocol with the command and the file. For example: Code: mplayer file:///path/to/file.avi It is also possible to load in files with the file protocol when you want to only pass in the file without loading the file into memory. This allows you to pass in a file you know is smaller than your computer's ram. For example: Code: mplayer file:///path/to/file.avi The mplayer command only accepts a file protocol URI of the form: Code: file:///path/to/file.avi The mplayer command only supports one file at a time. For example: Code: mplayer file:///path/to/file.avi The mplayer command does not support multiple files at once. For example: Code: mplayer file:///path/to/file.avi file:///path/to/file2.avi The mplayer command ignores any protocol handlers, if you pass them

jMencode is a thin Java application that makes it a trivial task to convert movies into the MPEG-4 file format. It aims to be both simple to use and fully featured. The Features: - Fast encode and decoding, doesn't try to model MPEG-2 videos perfectly (it misses frame rate up conversion, and doesn't keep the number of frames constant) - Support video and audio streams with different bit rates - Support for AVC, H.264, MPEG-4 AVC, HEVC/H.265 and VP9. AVC and H.264 are handled by FreeSWITCH, and VP9 and HEVC by FFmpeg. - Support for manual conversion through the command line. It is recommended to use jMencode when it will be run in a script. - Allows the user to configure the output conversion parameters (bitrate, size and number of frames) - Compresses the input data using one of the available formats. Works with mp4, avi, xvid, divx and mkv. The format used will be the one associated to the output file. - Compresses the input data to the best available format. Works with mp4, avi, xvid and mkv. The format used will be the one associated to the output file. - Encodes audio streams - Separate video and audio encoders - Supports all input stream formats supported by FreeSWITCH (FFmpeg) - Optionally, it can

The only supported formats are avi, xvid, mkv, divx - Synchronizes videos and audio streams - Supports autogeneration of subtitles. You may specify subtitle file as well as target language, format and quality. - Optionally, it can encode video and audio streams using "anamorphic" (4:3) or "square" (16:9) aspect ratio. - Optionally, it can decode H.264 at low resolution, or in combination with FFmpeg H.264 support, in order to gain better performance in such cases. - Supports multiple threads (up to 16). - Flexible configuration options, should 6a5afdab4c
